# Outline

- ▶ Mixture model: a generative model  
new:  $L_1$  penalization for variable selection;  
Pan et al (2006, Bioinformatics)
- ▶ Transductive SVM (TSVM):  
Wang, Shen & Pan (2007, CM; 2009, JMLR)
- ▶ Self-supervised learning: DL  
Chen et al (2020)

# Introduction

- ▶ Biology: Do human blood outgrowth endothelial cells (BOECs) belong to or are closer to large vessel endothelial cells (LVECs) or microvascular endothelial cells (MVECs)?
- ▶ Why important? BOECs are being explored for efficacy in endothelial-based gene therapy (Lin et al 2002), and as being useful for vascular diagnostic purposes (Hebbel et al 2005); in each case, it is important to know whether BOEC have characteristics of MVECs or of LVECs.

- ▶ Jiang (2005) conducted a genome-wide comparison: microarray gene expression profiles for BOEC, LVEC and MVEC samples were clustered; it was found that BOEC samples tended to cluster together with MVEC samples, suggesting that BOECs were closer to MVECs.
- ▶ Two potential shortcomings:
  1. Used hierarchical clustering; ignoring the known classes of LVEC and MVEC samples;  
Alternative? Semi-supervised learning: treating LVEC and MVEC as known while BOEC unknown (see McLachlan and Basford 1988; Zhu 2006 for reviews).  
Here it requires learning a novel class: BOEC may or may not belong to LVEC or MVEC.
  2. Used only 37 genes that best discriminate b/w LVEC and MVEC.  
Important: result may critically depend on the features or genes being used; the few genes might not reflect the whole picture.  
Alternative? Start with more genes; but ...  
A dilemma: too many genes might lead to covering true clustering structures; to be shown later.

- ▶ For high-dimensional data, necessary to have feature selection, preferably embedded within the learning framework – automatic/simultaneous feature selection.
- ▶ In contrast to sequential methods: first selecting features and then fitting/learning a model;  
Pre-selection may perform terribly;  
Why: selected features may not be relevant at all to uncovering interesting clustering structures, due to the separation between the two steps.
- ▶ A penalized mixture model: semi-supervised learning; automatic variable selection simultaneously with model fitting.

# Semi-Supervised Learning via Standard Mixture Model

- ▶ Data

Given  $n$   $K$ -dimensional obs's:  $x_1, \dots, x_n$ ; the first  $n_0$  do not have class labels while the last  $n_1$  have.

There are  $g = g_0 + g_1$  classes: the first  $g_0$  unknown/novel classes to be discovered. while the last  $g_1$  known.

$z_{ij} = 1$  iff  $x_j$  is **known** to be in class  $i$ ;  $z_{ij} = 0$  o/w.

Note:  $z_{ij}$ 's are missing for  $1 \leq j \leq n_0$ .

- ▶ The log-likelihood is

$$\log L(\Theta) = \sum_{j=1}^{n_0} \log \left[ \sum_{i=1}^g \pi_i f_i(x_j; \theta_i) \right] + \sum_{j=n_0+1}^n \log \left[ \sum_{i=1}^g z_{ij} \pi_i f_i(x_j; \theta_i) \right].$$

- ▶ Common to use the EM to get MLE.

# Penalized Mixture Model

- ▶ Penalized log-likelihood: use a weighted  $L_1$  penalty;

$$\log L_P(\Theta) = \log L(\Theta) + \lambda \sum_i \sum_k w_{ik} |\mu_{ik}|,$$

where  $w_{ik}$ 's are weights to be given later.

- ▶ Penalty: model regularization; Bayesian connection.
- ▶ Assume that the data have been standardized so that each feature has sample mean 0 and sample variance 1.
- ▶ Hence, for any  $k$ , if  $\mu_{1k} = \dots = \mu_{gk} = 0$ , then feature  $k$  will not be used.
- ▶  $L_1$  penalty serves to obtain a sparse solution:  $\mu_{ik}$ 's are automatically set to 0, realizing variable selection.

- ▶ EM algorithm: E-step and M-step for other parameters are the same as in the usual EM, except M-step for  $\mu_{ik}$ ;

$$\hat{\pi}_i^{(m+1)} = \sum_{j=1}^n \tau_{ij}^{(m)} / n, \quad (1)$$

$$\hat{\sigma}_k^{2,(m+1)} = \sum_{i=1}^g \sum_{j=1}^n \tau_{ij}^{(m)} (x_{jk} - \hat{\mu}_{ik}^{(m)})^2 / n, \quad (2)$$

$$\hat{\mu}_i^{(m+1)} = \text{sign}(\tilde{\mu}_i^{(m+1)}) \left( |\tilde{\mu}_i^{(m+1)}| - \frac{\lambda}{\sum_j \tau_{ij}^{(m)}} V^{(m)} w_i \right)_+ \quad (3)$$

where

$$\tau_{ij}^{(m)} = \begin{cases} \frac{\pi_i^{(m)} f_i(x_j; \theta_i^{(m)})}{f(x_j; \Theta^{(m)})}, & \text{if } 1 \leq j \leq n_0 \\ z_{ij}, & \text{if } n_0 < j \leq n \end{cases} \quad (4)$$

$$\tilde{\mu}_i^{(m+1)} = \sum_{j=1}^n \tau_{ij}^{(m)} x_j / \sum_{j=1}^n \tau_{ij}^{(m)} \quad (5)$$

# Model Selection

- ▶ To determine  $g_0$  (and  $\lambda$ ), use BIC (Schwartz 1978)

$$BIC = -2 \log L(\hat{\Theta}) + \log(n)d,$$

where  $d = g + K + gK - 1$  is the total number of unknown parameters in the model; the model with a minimum BIC is selected (Fraley and Raftery 1998).

- ▶ For the penalized mixture model, Pan and Shen (2007) proposed a modified BIC:

$$BIC = -2 \log L(\hat{\Theta}) + \log(n)d_e,$$

where  $d_e = g + K + gK - 1 - q = d - q$  with  $q = \#\{\hat{\mu}_{ik} : \hat{\mu}_{ik} = 0\}$ , an estimate of the “effective” number of parameters.

# Real Data

- ▶ 28 LVEC and 25 MVEC samples from Chi et al (2003); cDNA arrays.
- ▶ 27 BOEC samples; Affy arrays.
- ▶ Combined data: 9289 unique genes in both data.
- ▶ Need to minimize systematic bias due to different platforms.
- ▶ 6 human umbilical vein endothelial cell (HUVEC) samples from each of the two datasets.
- ▶ Jiang studied 64 possible combinations of a three-step normalization procedure and identified the one maximizing the extent of mixing of the 12 HUVEC samples.
- ▶ Normalized the data in the same way

- ▶  $g_0 = 0$  or  $1$ ;  $g_1 = 2$ .
- ▶ 6 models: 1) 3 methods: standard, penalized with  $w = 0$ , and penalized with  $w = 1$ ; 2 values of  $g_0$ : 0 or 1.
- ▶ The EM randomly started 20 times with the starting values from the K-means output.
- ▶ At convergence, used the posterior probabilities to classify BOEC samples, as well as LVEC and MVEC samples.
- ▶ Used 3 sets of the genes in the starting model.
- ▶ Using 37 genes best discriminating LVEC and MVEC:

**Table:** Semi-supervised learning with 37 genes. The BIC values of the six models (from left to right and from top to bottom) were 2600, 2549, 2510, 2618, 2520 and 2467 respectively.

	$g_0 = 0, g_1 = 2$					
	$\lambda = 0$		$\lambda = 5, w = 0$		$\lambda = 2, w = 1$	
Sample	1	2	1	2	1	2
BOEC	1	26	6	21	0	27
LVEC	24	4	25	3	25	3
MVEC	2	23	3	22	2	23

  

	$g_0 = 1, g_1 = 2$								
	$\lambda = 0$			$\lambda = 6, w = 0$			$\lambda = 3, w = 1$		
Sample	1	2	3	1	2	3	1	2	3
BOEC	13	1	13	17	1	9	16	0	11
LVEC	1	24	3	2	24	2	1	25	2
MVEC	0	1	24	2	1	24	0	2	23

**Table:** Numbers of the 37 features with zero mean estimates.

	$g_0 = 0, g_1 = 2$							
	$\lambda = 5, w = 0$			$\lambda = 2, w = 1$				
Cluster	1	2	All	1	2	All		
#Zeros	11	11	11	14	18	14		
	$g_0 = 1, g_1 = 2$							
	$\lambda = 6, w = 0$				$\lambda = 3, w = 1$			
Cluster	1	2	3	All	1	2	3	All
#Zeros	21	10	11	5	24	18	20	12

- ▶ Using top 1000 genes discriminating LVEC and MVEC;
- ▶ Using top 1000 genes with largest sample variances;
- ▶ —similar results!

# TSVM

- ▶ Labeled data:  $(x_i, y_i)$ ,  $i = 1, \dots, n_l$ ;  
Unlabeled data:  $(x_i)$ ,  $i = n_l + 1, \dots, n$ .
- ▶ SVM: consider linear kernel; i.e.

$$f(x) = \beta_0 + \beta'x.$$

- ▶ Estimation in SVM:

$$\min_{\beta_0, \beta} \sum_{i=1}^{n_l} L(y_i f(x_i)) + \lambda_1 \|\beta\|^2$$

- ▶ TSVM: aim the same  $f(x) = \beta_0 + \beta'x$ .

- ▶ Estimation in TSVM:

$$\min_{\{y_{n_l+1}^*, \dots, y_n^*\}, \beta_0, \beta} \sum_{i=1}^{n_l} L(y_i f(x_i)) + \lambda_1 \|\beta\|^2 + \lambda_2 \sum_{i=n_l+1}^n L(y_i^* f(x_i))$$

- ▶ Equivalently (Wang, Shen & Pan 2007; 2009, JMLR),

$$\min_{\beta_0, \beta} \sum_{i=1}^{n_l} L(y_i f(x_i)) + \lambda_1 \|\beta\|^2 + \lambda_2 \sum_{i=n_l+1}^n L(|f(x_i)|)$$

- ▶ Computational algorithms DO matter!
- ▶ Active research going on: e.g. with EHRs

**Table: Linear learning:** Averaged test errors as well as the estimated standard errors (in parenthesis) of SVM with labeled data alone, TSVM<sup>Light</sup>, and TSVM<sup>DCA</sup>, over 100 pairs of training and testing samples, in the simulated and benchmark examples.

Data	SVM	TSVM <sup>Light</sup>	TSVM <sup>DCA</sup>

# Self-Supervised Learning

- ▶ Ref: Chen et al (2020);  
also called contrastive learning, semi-supervised learning.
- ▶ DL: used for pre-training/transfer learning; self-training.
- ▶  $f()$ : a NN *base encoder*,  
a **target** NN up to the layer prior/close to output.  
Representation learning.
- ▶  $g()$ : A small NN *projection head*.  
e.g. a FFN with 1 hidden layer,  $g(h) = W_2\sigma(W_1h)$ .
- ▶ To train a new NN  $f + g$ :  $f()$  then  $g()$ .
- ▶ Data augmentation: data/image transformations, e.g.,  
random cropping + resizing; rotating; cutting out; color  
distortions; Gaussian blurring; ...

- ▶  $x_i \implies \tilde{x}_{2i-1} = t(x_i), \tilde{x}_{2i} = t'(x_i).$
- ▶  $h_{2i-1} = f(\tilde{x}_{2i-1}), h_{2i} = f(\tilde{x}_{2i}),$   
 $z_{2i-1} = g(h_{2i-1}), z_{2i} = g(h_{2i})$
- ▶ Contrastive loss:  $s_{i,j} = z_i^T z_j / (\|z_i\| \|z_j\|),$

$$L(i,j) = -\log \frac{\exp(s_{i,j}/\tau)}{\sum_{k=1}^{2N} I(k \neq i) \exp(s_{i,k}/\tau)},$$

- ▶ The NN " $f + g$ " is trained with each minibatch by

$$\min \frac{1}{2N} \sum_{k=1}^N [L(2k-1, 2k) + L(2k, 2k-1)].$$

- ▶ Take  $f()$  and throw away  $g()$
- ▶ Then train " $f()$  plus output layer(s)" with some labeled data.  
**better** than training " $f()$  plus output layer(s)" from scratch.  
 Note: **no labels** for  $x_i$ 's!
